Problem 3.1 (continued)

Identify (underline) the problem number. Each new problem **MUST** begin on a new page. Clearly indicate if this is a problem continuing from a previous page.

Given: Structure as illustrated below, with applied external forces.

Required: Determine the moment of F about point A at the left end of the beam.

Problem solutions must begin with a statement of the problem, and the required components to determine. This can be a brief summary.

Figures should be drawn neatly (with a ruler or handy template that accompanies the text). A sloppy drawing cannot convey information clearly. Neatness Counts!

The solution should begin with an outline of the steps, followed by a systematic approach to the solution.

Solution:

- The moment of the force is equal to the force magnitude times the perpendicular distance, d , from point A to the line of action of the force.
- Perpendicular distance, $d = l \sin \theta = 10 \sin(70^\circ) = 9.4 \text{ ft}$.
- Moment, $M_o = Fd = 300(9.40) = 2819 \text{ lb}\cdot\text{ft}$.

$$M_o = 2819 \text{ lb}\cdot\text{ft} \curvearrowright$$

The solution must be highlighted (inside a box or circle), and contain the correct units (including direction). Watch extraneous digits!
